

Miniproject - Introduction to Schemes

Candidate Number: 1059926

March 31, 2022

In this miniproject, we want to study the Proj-construction in the theory of schemes, that can be used to associate a scheme given a graded ring. In particular, it is very closely related to projective space (hence the name).

We begin the work by defining the scheme $\text{Proj}(S)$ for a graded ring S , and showing that it is well-defined. Furthermore, we study some very basic properties. Then we focus on the case that our graded ring S is an R -algebra, in particular, we are interested in the case of the polynomial ring $R[x_0, \dots, x_n]$. This case is important, since it yields the projective space \mathbb{P}_R^n .

Finally, we use the theory developed in the work to prove the main result, namely that projective space is a proper scheme. We present two proofs of this, one relatively short and concrete (but complicated) one, relying on commutative algebra. The other proof is the standard proof, as presented in works like [Har77]. For the sake of brevity, we will only present parts of this proof, but try to give a little bit of intuition.

1 Definition of Proj

First of all, we introduce the fundamental object used in the Proj-construction.

Definition 1.1. A *graded ring*¹ S is a ring S with a decomposition $S = \bigoplus_{d \in \mathbb{Z}} S_d$ into subgroups $S_i \subseteq S$ (w.r.t. addition in S) such that $S_i \cdot S_j \subseteq S_{i+j}$ for all $i, j \in \mathbb{Z}$. We call S *naturally graded*, if $S_i = \{0\}$ for $i < 0$. Write further $S_+ := \sum_{d \geq 0} S_d$. For a homogeneous $f \in S_d$ say that $\deg(f) := d$ is its *degree*.

An element $f \in S$ is called *homogeneous* (of degree n), if $f \in S_n$. An ideal $I \leq S$ is called *homogeneous*, if it has a set of homogeneous generators.

From now on let S be a naturally graded ring.

¹Unlike most authors, we consider graded rings with homogeneous elements of negative degree (i.e. not naturally graded rings), so that we can talk about the grading of a localization. Namely, if $T \subseteq S$ is a multiplicative subset containing only homogeneous elements of a graded ring S , then $T^{-1}S$ has the canonical grading given by $\deg(f/t) = \deg(f) - \deg(t)$.

Definition 1.2. Define the *projective spectrum* $\text{Proj}(S)$ as all homogeneous prime ideals that do not contain the “irrelevant ideal” S_+

$$\text{Proj}(S) := \{\mathfrak{p} \in \text{Spec}(S) \mid \mathfrak{p} \text{ homogeneous, } S_+ \not\subseteq \mathfrak{p}\}$$

This becomes a topological space by endowing it with the *Zariski-topology* on $\text{Proj}(S)$, given by the open sets

$$D_+(\mathfrak{a}) := \{\mathfrak{p} \in \text{Proj}(S) \mid \mathfrak{a} \not\subseteq \mathfrak{p}\}$$

for any homogeneous ideal $\mathfrak{a} \leq S$.

Proposition 1.3. *The above definition is well-defined, i.e. the sets $D_+(\mathfrak{a})$ indeed form a topology on $\text{Proj}(S)$.*

Proof. Clearly $\text{Proj}(S) = D_+(\langle 1 \rangle)$ and $\emptyset = D_+(\langle 0 \rangle)$ are open. To show that finite intersections and arbitrary unions of open sets are open, notice that as usual

$$D_+(\mathfrak{a}) \cap D_+(\mathfrak{b}) = D_+(\mathfrak{a}\mathfrak{b}) \quad \text{and} \quad \bigcup_{\mathfrak{a} \in \mathcal{A}} D_+(\mathfrak{a}) = D_+(\mathfrak{b}) \quad \text{where } \mathfrak{b} = \sum_{\mathfrak{a} \in \mathcal{A}} \mathfrak{a}$$

Clearly the ideals $\mathfrak{a}\mathfrak{b}$ and \mathfrak{b} are again homogeneous. □

As opposed to Hartshorne [Har77], our approach to construct a sheaf of rings on $\text{Proj}(S)$ will be similar to the construction of $\text{Spec}(R)$, i.e. we will first specify $\mathcal{O}_{\text{Proj}(S)}$ on a topological basis. This is also the definition used in [Stacks, Tag 01M6].

Lemma 1.4. *For a homogeneous ideal \mathfrak{a} have $D_+(\mathfrak{a}) = D_+(\mathfrak{a}S_+)$.*

Proof. The inclusion \supseteq is clear, as $\mathfrak{a}S_+ \subseteq \mathfrak{a}$. So assume there is a $\mathfrak{p} \in D_+(\mathfrak{a})$. Since $\mathfrak{p} \in \text{Proj}(S)$ find $S_+ \not\subseteq \mathfrak{p}$ and by assumption, $\mathfrak{a} \not\subseteq \mathfrak{p}$. Thus there are $s \in S_+$ and $a \in \mathfrak{a}$ with $a, s \notin \mathfrak{p}$. Since \mathfrak{p} is prime, it follows that $as \notin \mathfrak{p}$ and so $\mathfrak{a}S_+ \not\subseteq \mathfrak{p}$. □

Proposition 1.5. *The sets $D_+(f) := D_+(\langle f \rangle)$ for homogeneous $f \in S_+$ form a basis of the topology on $\text{Proj}(S)$.*

Proof. Clearly $\langle f \rangle$ is a homogenous ideal, so $D_+(f)$ is open. For any homogeneous ideal $\mathfrak{a} = \langle f_i \mid i \in I \rangle$ with $f_i \in S$ homogeneous have that $D_+(\mathfrak{a}) = D_+(\mathfrak{a}S_+)$ by Lemma 1.4, so we can assume wlog that all $f_i \in S_+$. Now have

$$D_+(\mathfrak{a}) = \bigcup_{i \in I} D_+(f_i)$$

as $\mathfrak{a} \not\subseteq \mathfrak{p}$ implies there is some $g = \sum_{i \in I} g_i f_i \notin \mathfrak{p}$, with $g_i \in S$. Hence, at least one $g_i f_i \notin \mathfrak{p}$ and so $f_i \notin \mathfrak{p}$, thus $\mathfrak{p} \in D_+(f_i)$. It follows that the $D_+(f)$ generate the topology on $\text{Proj}(S)$, so it is left to show that they are a basis.

Consider $\mathfrak{p} \in D_+(f) \cap D_+(g)$, so $f, g \notin \mathfrak{p}$. Since \mathfrak{p} is prime, it follows that $fg \notin \mathfrak{p}$ and so $D_+(fg) \subseteq D_+(f) \cap D_+(g)$ is an open neighborhood of \mathfrak{p} . □

Lemma 1.6. *Let $\mathfrak{p} \leq S$ be a prime ideal. Then*

$$\mathfrak{p}' := \langle f \in \mathfrak{p} \mid f \text{ homogeneous} \rangle \leq S$$

is a (homogeneous) prime ideal.

Proof. Consider $f, g \in S$ with $fg \in \mathfrak{p}'$ and assume $f, g \notin \mathfrak{p}'$. Write $f = \sum_d f_d$ and $g = \sum_d g_d$ with $f_d, g_d \in S_d$. So

$$\sum_{i,j} f_i g_j = \sum_n \sum_{i+j=n} f_i g_j \in \mathfrak{p}'$$

Since \mathfrak{p}' is homogeneous, it follows that

$$\sum_{i+j=n} f_i g_j \in \mathfrak{p}'$$

for all $n \in \mathbb{Z}$. Let now d resp. e be maximal such that $f_d \notin \mathfrak{p}'$ resp. $g_e \notin \mathfrak{p}'$. We have

$$f_d g_e + \sum_{\substack{i+j=d+e \\ (i,j) \neq (d,e)}} \underbrace{f_i g_j}_{\in \mathfrak{p}'} = \sum_{i+j=d+e} f_i g_j \in \mathfrak{p}'$$

and so $f_d g_e \in \mathfrak{p}' \subseteq \mathfrak{p}$. Since \mathfrak{p} is prime, it follows that $f_d \in \mathfrak{p}$ or $g_e \in \mathfrak{p}$. However both f_d and g_e are homogeneous, so $f_d \in \mathfrak{p}'$ or $g_e \in \mathfrak{p}'$, a contradiction. \square

Lemma 1.7 (“Covering Trick”). *Let $f, f_i \in S_+$ be homogeneous. Then $D_+(f) \subseteq \bigcup_i D_+(f_i)$ if and only if $f^n \in \langle f_i \mid i \rangle$ for some $n \in \mathbb{N}$*

Proof. The direction \Leftarrow is clear. So assume $D_+(f) \subseteq \bigcup_i D_+(f_i)$. If no f^n is in $\mathfrak{a} := \langle f_i \mid i \rangle$, then f is not nilpotent in S/\mathfrak{a} and so $(S/\mathfrak{a})_f$ is not the zero ring. Hence, $(S/\mathfrak{a})_f$ has a prime ideal, and its preimage under $S \rightarrow S/\mathfrak{a} \rightarrow (S/\mathfrak{a})_f$ yields a prime ideal \mathfrak{p}' containing \mathfrak{a} and not containing f . Since $f \in S_+$ note that $S_+ \not\subseteq \mathfrak{p}'$ and as both f and \mathfrak{a} are homogeneous, Lemma 1.6 yields now that $\langle g \in \mathfrak{p}' \mid g \text{ homogeneous} \rangle$ is a prime ideal in $D_+(f)$ but not in $\bigcup_i D_+(f_i)$, contradicting the assumption. \square

Corollary 1.8. *If $D_+(g) \subseteq D_+(f)$ with $f, g \in S_+$, then there is a homogeneous $h \in S$ such that $g^n = fh$ for some $n \in \mathbb{N}$.*

Proposition 1.9. *Let $B = \{D_+(f) \mid f \in S_+ \text{ homogeneous}\}$. The functor²*

$$\begin{aligned} \mathcal{F} : \text{Top}(\text{Proj}(S))|_B &\rightarrow \mathbf{Ring}, \quad D_+(f) \mapsto (S_f)_0 \\ (D_+(fg) \subseteq D_+(f)) &\mapsto \left(\cdot|_{D_+(fg)} : \frac{s}{f^n} \mapsto \frac{sg^n}{(fg)^n} \right) \end{aligned}$$

is a B -sheaf on B (here $\text{Top}(X)$ is the category given by the open sets of X and their inclusion, as defined in the lecture).

²The map on arrows is well-defined by Corollary 1.8.

Proof. This is exactly the proof from the lecture, Section 1.12. Note that we have all necessary ingredients, in particular the Covering Trick 1.7. Hence, the only thing to note is that the gluing produces a homogeneous global section if one starts with homogeneous local sections. It is easy to check that this is indeed the case. \square

Now the B-sheaf extension theorem from the lecture (from Section 1.11) yields the following corollary.

Corollary 1.10. *The B-sheaf \mathcal{F} can be (uniquely, up to isomorphism) extended to a sheaf $\mathcal{O}_{\text{Proj}(S)}$ on $\text{Proj}(S)$.*

The next two lemmas are based on [Har77, Prop. II.2.5] and will be used to deduce that $(\text{Proj}(S), \mathcal{O}_{\text{Proj}(S)})$ is a scheme.

Lemma 1.11. *For $\mathfrak{p} \in \text{Proj}(S)$, the stalk*

$$\mathcal{O}_{\text{Proj}(S), \mathfrak{p}} = (T^{-1}S)_0$$

is a local ring, where $T = \{f \notin \mathfrak{p} \mid f \text{ homogeneous}\}$ contains all homogeneous elements not in \mathfrak{p} .

Proof. Consider the ideal

$$\mathfrak{m} = \left\{ \frac{f}{g} \in (T^{-1}S)_0 \mid f \in \mathfrak{p} \right\}$$

We claim this is the unique maximal ideal of $(T^{-1}S)_0$.

First, note that $1 \notin \mathfrak{m}$ as otherwise, there would be $f/g \in T^{-1}S$, $f \in \mathfrak{p}$ with $t(f-g) = 0$ for some $t \in T$. However then $tg = tf \in \mathfrak{p}$, and so $g \in \mathfrak{p}$ (as $t \notin \mathfrak{p}$), contradicting $g \in T$.

Now consider an ideal \mathfrak{a} such that $\mathfrak{a} \setminus \mathfrak{m} \neq \emptyset$, i.e. there is $f/g \in \mathfrak{a} \setminus \mathfrak{m}$. Then $f \in T$ as f homogeneous (since $f/g \in (T^{-1}S)_0$ is homogeneous of degree 0) and $f \notin \mathfrak{p}$. Thus $g/f \in (T^{-1}S)_0$ and so $f/g \in (T^{-1}S)_0^*$, which implies $\mathfrak{a} = \langle 1 \rangle$. \square

Lemma 1.12. *For $f \in S_+$ homogeneous have that $(D_+(f), \mathcal{O}_{\text{Proj}(S)}|_{D_+(f)})$ is an affine scheme.*

Proof. Let $R = (S_f)_0$. Consider the map

$$\phi : D_+(f) \rightarrow \text{Spec}(R), \quad \mathfrak{p} \mapsto \mathfrak{p}S_f \cap R$$

Note that it is continuous, as the preimage of some basic open set D_{g/f^n} is $D_+(fg) \subseteq D_+(f)$ open. Furthermore, have the map

$$\phi' : \text{Spec}(R) \rightarrow D_+(f), \quad \mathfrak{p} \mapsto \mathfrak{p}S_f \cap S$$

which is also continuous, as the preimage of some basic open set $D_+(fg)$ is D_{g^n/f^m} where $n \deg(g) = m \deg(f)$, $(n, m) \neq (0, 0)$. Note that $\phi \circ \phi' = \text{id}_{\text{Spec}(R)}$ because for $\mathfrak{p} \leq R$ have $\mathfrak{p} \subseteq (\mathfrak{p}S_f \cap S)S_f \cap R$ and

$$(\mathfrak{p}S_f \cap S)S_f \cap R \subseteq \mathfrak{p}S_f \cap S_f \cap R = \mathfrak{p}S_f \cap (S_f)_0 = \mathfrak{p}$$

where the last equality holds, since $\mathfrak{p} \leq (S_f)_0$ is homogeneous.

To see that $\phi' \circ \phi = \text{id}_{D_+(f)}$, it suffices now to show that ϕ is injective (ϕ has a right-inverse, hence it is then bijective, and the one-sided inverse ϕ' is already the inverse). Let $\mathfrak{p}, \mathfrak{q} \leq S$ homogeneous primes with $f \notin \mathfrak{p}, \mathfrak{q}$. Assume there is $g \in \mathfrak{p} \setminus \mathfrak{q}$. Then

$$g^{\deg(f)} \in \mathfrak{p}S_f \setminus \mathfrak{q}S_f \Rightarrow \frac{g^{\deg(f)}}{f^{\deg(g)}} \in (\mathfrak{p}S_f \setminus \mathfrak{q}S_f) \cap R = (\mathfrak{p}S_f \cap R) \setminus (\mathfrak{q}S_f \cap R)$$

and so $\phi(\mathfrak{p}) \neq \phi(\mathfrak{q})$. Thus ϕ is a homeomorphism.

Now consider the natural transformation

$$\eta : \mathcal{O}_{\text{Spec}R} \Rightarrow \phi_* \left(\mathcal{O}_{\text{Proj}(S)} \Big|_{D_+(f)} \right)$$

given on basic open sets by

$$\eta_{D_{g/f^n}} : R_{g/f^n} \rightarrow (S_f)_0, \quad \frac{h/f^m}{(g/f^n)^l} \mapsto \frac{hf^{nl}}{g^l f^m}$$

Clearly this is a ring isomorphism, so η is a natural isomorphism. The claim follows. \square

Corollary 1.13. $(\text{Proj}(S), \mathcal{O}_{\text{Proj}(S)})$ is a scheme.

2 Projective space

For this section, let R be a ring and assume S is a graded R -algebra, i.e. S is a graded ring with $R \subseteq S_0$.

Definition 2.1. The scheme $\text{Proj}(S)$ naturally becomes a scheme over $\text{Spec}(R)$ via

$$\begin{aligned} f : \text{Proj}(S) &\rightarrow \text{Spec}(R), \quad \mathfrak{p} \mapsto \mathfrak{p} \cap R \\ f_{D_f}^\# : R_f &\rightarrow \mathcal{O}_{\text{Proj}(S)}(D_+(f)) = (S_f)_0, \quad r \mapsto r \end{aligned}$$

This is well-defined, as $R \subseteq S_0$ implies $R_f \subseteq (S_0)_f = (S_f)_0$ since $\deg(f) = 0$.

Proposition 2.2. The morphism $\text{Proj}(S) \rightarrow \text{Spec}(R)$ is separated.

Proof. This is the same proof as for [Stacks, Tag 01MC]. By Lemma 1.12 we find a cover $\text{Proj}(S) = \bigcup_i D_+(f_i)$ of affine opens. We use the characterization from the lecture and show that $D_+(f_i) \cap D_+(f_j)$ is an affine open and the canonical multiplication map

$$\mathcal{O}_{\text{Proj}(S)}(D_+(f_i)) \times \mathcal{O}_{\text{Proj}(S)}(D_+(f_j)) \rightarrow \mathcal{O}_{\text{Proj}(S)}(D_+(f_i) \cap D_+(f_j))$$

is surjective.

First note that $D_+(f_i) \cap D_+(f_j) = D_+(f_i f_j)$ which is affine open by Lemma 1.12. By definition, we have $\mathcal{O}_{\text{Proj}(S)}(D_+(f)) = (S)_0$ and so we have to show that

$$(S_{f_i})_0 \times (S_{f_j})_0 \rightarrow (S_{f_i f_j})_0, \quad (a, b) \mapsto ab$$

is surjective.

For $g/(f_i f_j)^n \in (S_{f_i f_j})_0$ we now have that

$$\frac{g f_j^r}{f_i^{n+t}} \cdot \frac{f_i^t}{f_j^{n+r}} = \frac{g}{(f_i f_j)^n}$$

where $r, t \in \mathbb{N}$ such that³ $\deg(f_j)n = \deg(f_i)t - \deg(f_j)r$.

Since $\deg(g) = (\deg(f_i) + \deg(f_j))n$ it follows that $\deg(g) + \deg(f_j)r = \deg(f_i)(n+t)$ and so both $g f_j^r / f_i^{n+t}$ and f_i^t / f_j^{n+r} have degree 0. Hence they are elements of $(S_{f_i})_0$ resp. $(S_{f_j})_0$ and the claim follows. \square

Now we want to define projective space, which is the object we study during the rest of this project. From now on, let $n \in \mathbb{N}$ and equip $R[x_0, \dots, x_n]$ with the standard grading.

Definition 2.3. *Projective n -space* is the scheme $\mathbb{P}_R^n := \text{Proj}(R[x_0, \dots, x_n])$ over $\text{Spec}(R)$.

Lemma 2.4. *If $\text{Spec}(R)$ is irreducible, then $\mathfrak{N}(R)R[x_0, \dots, x_n] = \mathfrak{N}(R[x_0, \dots, x_n])$.*

Proof. Clearly $\mathfrak{N}(R)R[x_0, \dots, x_n] \subseteq \mathfrak{N}(R[x_0, \dots, x_n])$, as for $\sum_{i=1}^m f_i r_i$ with $f_i^n = 0$ have that

$$\left(\sum_{i=1}^m f_i r_i \right)^{mn} = \sum_{\substack{1 \leq i_1, \dots, i_{mn} \leq m \\ \text{as at least one } i \text{ repeats at least } n \text{ times in } i_1, \dots, i_{mn}}} \underbrace{f_{i_1} \dots f_{i_{mn}}}_{=0} r_{i_1} \dots r_{i_{mn}}$$

Now note that $\mathfrak{N}(R[x_0, \dots, x_n]) \subseteq \mathfrak{a}$ for all prime ideals \mathfrak{a} , and the claim follows since $\mathfrak{N}(R)$ and thus $\mathfrak{N}(R)R[x_0, \dots, x_n]$ is prime by assumption that $\text{Spec}(R)$ is irreducible. \square

Proposition 2.5. *Assume $\text{Spec}(R)$ is irreducible. Then \mathbb{P}_R^n is an irreducible scheme.*

Proof. We show that $D_+(x_0) \subseteq \mathbb{P}_R^n$ is dense. The claim then follows, as any two nonempty, disjoint open sets give nonempty, disjoint open sets in D_{x_0} which is isomorphic to the irreducible⁴ affine scheme $\text{Spec}(R[x_0, \dots, x_n]_{x_0})_0$ by Lemma 1.12.

So consider any nonempty basic open $D_+(f) \subseteq \mathbb{P}_R^n$ and find that $D_+(f) \cap D_+(x_0) = D_+(fx_0)$. By assumption, $\mathfrak{N}(R)$ is a prime ideal and so fx_0 is not nilpotent (unless f were nilpotent, but then $D_+(f) = \emptyset$), i.e. the ring $R[x_0, \dots, x_n]_{fx_0}$ is not the zero ring. Hence, it has a maximal ideal \mathfrak{m} . Let \mathfrak{p} be the preimage of \mathfrak{m} under the localization map $R[x_0, \dots, x_n] \rightarrow R[x_0, \dots, x_n]_{fx_0}$, which is clearly prime with $fx_0 \notin \mathfrak{p}$. By Lemma 1.6, we now see that

$$\mathfrak{p}' := \langle f \in \mathfrak{p} \mid f \text{ homogeneous} \rangle \leq R[x_0, \dots, x_n]$$

is a homogeneous prime ideal, and since $fx_0 \notin \mathfrak{p} \supseteq \mathfrak{p}'$, we see that $S_+ \not\subseteq \mathfrak{p}'$, i.e. $\mathfrak{p}' \in \text{Proj}(R[x_0, \dots, x_n])$. Now it follows that $\mathfrak{p}' \in D_+(fx_0)$, so $D_+(fx_0) \neq \emptyset$. \square

Proposition 2.6. *Assume R is reduced. Then \mathbb{P}_R^n is a reduced scheme.*

³This exists, since $\gcd(\deg(f_i), \deg(f_j)) \mid \deg(f_j) \mid \deg(f_j)n$.

⁴This is obviously irreducible, as $R[x_0, \dots, x_n]/\mathfrak{N}(R[x_0, \dots, x_n]) = (R/\mathfrak{N}(R))[x_0, \dots, x_n]$ is integral by assumption and Lemma 2.4.

Proof. By the lecture, it suffices to show that each $\mathcal{O}_{\mathbb{P}_R^n}(D_+(x_i)) \cong \text{Spec}(R[x_0, \dots, x_n]_{(x_i)})_0$ is reduced. However this is trivial, as taking the polynomial ring $R[x_0, \dots, x_n]$ preserves reducedness, and localizing (and of course taking the subring S_0) also do. \square

Corollary 2.7. *Assume R is integral. Then \mathbb{P}_R^n is an integral scheme.*

Proposition 2.8. *The morphism $\mathbb{P}_R^n \rightarrow \text{Spec}(R)$ is of finite type.*

Proof. First note that \mathbb{P}_R^n is covered by a finite number of affine opens $D_+(x_i)$ where the canonical morphisms

$$D_+(x_i) \cong \text{Spec}(R[x_0, \dots, x_n]_{(x_i)})_0 \rightarrow \text{Spec}(R)$$

are quasi-compact (they are induced by ring homomorphisms $R \rightarrow (R[x_0, \dots, x_n]_{(x_i)})_0$), hence \mathbb{P}_R^n is quasi-compact.

To see that it is locally of finite type, show that there is the cover by affine opens $\mathbb{P}_R^n = \bigcup_i D_+(x_i)$ such that the ring homomorphisms $R \rightarrow \mathcal{O}_{\mathbb{P}_R^n}(D_+(x_i))$ are of finite type. This is clearly the case, as

$$\mathcal{O}_{\mathbb{P}_R^n}(D_+(x_i)) = (R[x_0, \dots, x_n]_{(x_i)})_0 \cong R[y_0, \dots, y_{i-1}, y_i, \dots, y_n]$$

is a finitely generated R -algebra. \square

Corollary 2.9. *If k is an algebraically closed field, then \mathbb{P}_k^n is a variety.*

3 Projective space is proper

We already know that \mathbb{P}_R^n is separated and of finite type over $\text{Spec}(R)$, now we want to show that it is proper. Both in Hartshorne [Har77] and the Stacks project [Stacks], and in every other source I could find, this is done using the “valuative criterion for properness” (see also Section 4.1). However, its proof is apparently quite lengthy and requires a lot of abstract algebra. In the following, I tried to find a simpler and shorter proof. That was only partially successful, as the proof I came up with is shorter, but definitely not simpler. However, it gives a slightly different perspective onto the issue, which is quite nice.

I am slightly surprised that the following lemma was to be found nowhere, except in [Stacks, Tag 03IT] (for general algebraic spaces). It seems to be the kind of characterization I would expect to find in most textbooks.

Lemma 3.1. *A scheme X over $\text{Spec}(R)$ is universally closed, if for all ring homomorphisms $R \rightarrow S$ satisfy the following: The base change map $X \times_{\text{Spec}(R)} \text{Spec}(S) \rightarrow \text{Spec}(S)$, i.e. the map that makes the diagram*

$$\begin{array}{ccc} \text{Spec}(S) \times_{\text{Spec}(R)} X & \longrightarrow & X \\ \downarrow & & \downarrow \\ \text{Spec}(S) & \longrightarrow & \text{Spec}(R) \end{array}$$

commute, is closed.

Proof. Consider any scheme Y over $\mathrm{Spec}(R)$. We have to show that the map $\pi : Y \times_{\mathrm{Spec}(R)} X \rightarrow Y$ that makes the diagram

$$\begin{array}{ccc} Y \times_{\mathrm{Spec}(R)} X & \longrightarrow & X \\ \pi \downarrow & & \downarrow \\ Y & \longrightarrow & \mathrm{Spec}(R) \end{array}$$

commute, is closed.

Let $Y = \bigcup_i V_i$ be a cover by affine opens. For each i , note that the diagram

$$\begin{array}{ccc} \pi^{-1}(V_i) & \longrightarrow & X \\ \pi_i := \pi|_{\pi^{-1}(V_i)} \downarrow & & \downarrow \\ V_i & \longrightarrow & \mathrm{Spec}(R) \end{array}$$

commutes. By the universal property of $V_i \times_{\mathrm{Spec}(R)} X$ we now find a morphism

$$\psi : \pi^{-1}(V_i) \rightarrow V_i \times_{\mathrm{Spec}(R)} X$$

of schemes over $Y \times X$, i.e. the inclusion of $\pi^{-1}(V_i)$ into $Y \times_{\mathrm{Spec}(R)} X$ factors as

$$\pi^{-1}(V_i) \xrightarrow{\psi} V_i \times_{\mathrm{Spec}(R)} X \rightarrow Y \times_{\mathrm{Spec}(R)} X$$

Considering $V_i \times_{\mathrm{Spec}(R)} X$ as an open subscheme of $Y \times_{\mathrm{Spec}(R)} X$, we thus see that ψ must already be the identity and so $\pi^{-1}(V_i) \subseteq V_i \times_{\mathrm{Spec}(R)} X$. It follows that $\pi^{-1}(V_i) = V_i \times_{\mathrm{Spec}(R)} X$. By assumption, we now get that each π_i is closed, as $V_i \cong \mathrm{Spec}(\mathcal{O}_Y(V_i))$ is affine.

To show that π is closed, let $C \subseteq Y \times_{\mathrm{Spec}(R)} X$ be closed. Consider some $x \in Y \setminus \pi(C)$. Since the V_i cover Y , there is i such that $x \in V_i$. As $\pi_i = \pi|_{\pi^{-1}(V_i)}$ is closed, we see that

$$\pi(C) \cap V_i = \pi_i(C \cap \pi^{-1}(V_i)) \quad \text{is closed in } V_i$$

Hence there is an open neighborhood $U \subseteq V_i$ of x with $U \cap \pi(C) = \emptyset$. Now note that $V_i \subseteq Y$ is open, and so U is also an open neighborhood of x in Y . This holds for all $x \in Y \setminus \pi(C)$, hence $\pi(C)$ is closed. \square

Remark 3.2. Note that Proj is not functorial, in the sense that a homomorphism of graded rings $S \rightarrow T$ does not induce a natural morphism $\mathrm{Proj}(T) \rightarrow \mathrm{Proj}(S)$ (like Spec does). Namely, given $\alpha : S \rightarrow T$, we might want to consider

$$\mathrm{Proj}(T) \rightarrow \mathrm{Proj}(S), \quad \mathfrak{p} \mapsto \alpha^{-1}(\mathfrak{p})$$

However, in general this is not well-defined, as $\alpha^{-1}(\mathfrak{p})$ might contain S_+ ⁵.

If we further require the map $\alpha : S \rightarrow T$ to fulfill $T_+ \subseteq \alpha(S_+)T$, then this works out and we get a morphism

$$\begin{aligned} \text{Proj}(\alpha) : \text{Proj}(T) &\rightarrow \text{Proj}(S), \quad \mathfrak{p} \mapsto \alpha^{-1}(\mathfrak{p}), \\ \text{Proj}(\alpha)^\#_{D_+(f)} : \mathcal{O}_{\text{Proj}(S)}(D_+(f)) &\rightarrow \mathcal{O}_{\text{Proj}(T)}(D_+(\alpha(f))), \quad \frac{x}{y} \mapsto \frac{\alpha(x)}{\alpha(y)} \end{aligned}$$

Note that this is indeed a well-defined morphism, as for $\mathfrak{p} \in \text{Proj}(T)$ there is some $f \in T_+ \setminus \mathfrak{p}$ and by assumption, have $g \in S_+, t \in T$ with $\alpha(g)t = f$. Now $g \notin \alpha^{-1}(\mathfrak{p})$, as $g \in \alpha^{-1}(\mathfrak{p})$ would imply $\alpha(g) \in \mathfrak{p}$, thus $f = t\alpha(g) \in \mathfrak{p}$.

In particular, any ring homomorphism $R \rightarrow S$ induces a canonical morphism $\mathbb{P}_S^n \rightarrow \mathbb{P}_R^n$ of schemes, since the induced ring homomorphism $R[x_0, \dots, x_n] \rightarrow S[x_0, \dots, x_n]$ satisfies the above additional condition.

Lemma 3.3. *Let $R \rightarrow S$ be a ring homomorphism. Then the base change of \mathbb{P}_R^n is*

$$\mathbb{P}_R^n \times_{\text{Spec}(R)} \text{Spec}(S) \cong \mathbb{P}_S^n$$

as schemes over $\text{Spec}(S)$.

Proof. Consider the canonical map $\alpha : R[x_0, \dots, x_n] \rightarrow S[x_0, \dots, x_n]$ induced by $R \rightarrow S$. Note that

$$S \otimes_R (R[x_0, \dots, x_n]_f)_0 \cong (S[x_0, \dots, x_n]_{\alpha(f)})_0 \quad \text{via} \quad \iota_f : s \otimes \frac{r}{f^n} \mapsto \frac{s\alpha(r)}{\alpha(f)^n}$$

for all homogeneous $f \in R[x_0, \dots, x_n]$. By Lemma 1.12, we see that the basic open sets $D_+(x_i)$ form an affine open cover of \mathbb{P}_S^n . Furthermore, we have a cover by affine opens $D_+(x_i) \times_{\text{Spec}(R)} \text{Spec}(S)$ of $\mathbb{P}_R^n \times_{\text{Spec}(R)} \text{Spec}(S)$. Note that $\alpha(x_i) = x_i$. Together, we see that it suffices to show that the isomorphisms (induced by ι_{x_i})

$$\phi_i : D_+(x_i) = \text{Spec}(S[x_0, \dots, x_n]_{x_i})_0 \rightarrow D_+(x_i) \times_{\text{Spec}(R)} \text{Spec}(S)$$

glue to an isomorphism $\text{Proj}(S[x_0, \dots, x_n]) \rightarrow \mathbb{P}_R^n \times_{\text{Spec}(R)} \text{Spec}(S)$. By the gluing lemma, it suffices that the compatibility conditions are satisfied, i.e. for all i, j the diagram

$$\begin{array}{ccc} D_+(x_i) & \xrightarrow{\phi_i} & D_+(x_i) \times_{\text{Spec}(R)} \text{Spec}(S) \\ \nearrow & & \searrow \\ D_+(x_i) \cap D_+(x_j) = D_+(x_i x_j) & & \mathbb{P}_R^n \times_{\text{Spec}(R)} \text{Spec}(S) \\ \searrow & & \nearrow \\ D_+(x_j) & \xrightarrow{\phi_j} & D_+(x_j) \times_{\text{Spec}(R)} \text{Spec}(S) \end{array}$$

⁵Just consider the inclusion $R[x] \rightarrow R[x, y]$ and the ideal $\langle x \rangle \in \text{Proj}(R[x, y])$.

commutes.

For a prime ideal $\mathfrak{p} \in D_+(x_i x_j)$ have that

$$\phi_i(\mathfrak{p}) = \iota_{x_i}^{-1}(\mathfrak{p} \cap (S[x_0, \dots, x_n]_{x_i})_0) \in D_+(x_i) \times_{\text{Spec}(R)} \text{Spec}(S)$$

and so $x_j \notin \phi_i(\mathfrak{p})$, i.e. $\phi_i(\mathfrak{p}) \in D_+(x_i x_j) \times_{\text{Spec}(R)} \text{Spec}(S)$. Hence, both restrictions

$$\phi_i|_{D_+(x_i x_j)}, \phi_j|_{D_+(x_i x_j)} : D_+(x_i x_j) \rightarrow D_+(x_i x_j) \times_{\text{Spec}(R)} \text{Spec}(S)$$

map into $D_+(x_i x_j) \times_{\text{Spec}(R)} \text{Spec}(S)$. Now note that the diagram

$$\begin{array}{ccc} S \otimes_R (R[x_0, \dots, x_n]_{x_i})_0 & \xrightarrow{\iota_{x_i}} & (S[x_0, \dots, x_n]_{x_i})_0 \\ \downarrow & \swarrow S \otimes_R (R[x_0, \dots, x_n]_{x_j})_0 \xrightarrow{\iota_{x_j}} (S[x_0, \dots, x_n]_{x_j})_0 \searrow & \downarrow \\ S \otimes_R (R[x_0, \dots, x_n]_{x_i x_j})_0 & \xrightarrow{\iota_{x_i x_j}} & (S[x_0, \dots, x_n]_{x_i x_j})_0 \end{array}$$

commutes, and so the restrictions of ϕ_i resp. ϕ_j to $D_+(x_i x_j)$ are both induced by the homomorphism $\iota_{x_i x_j}$, hence they are equal. The claim follows. \square

This lemma also justifies the usual definition of *projective n -space over a scheme B* as

$$\mathbb{P}_B^n := B \times_{\text{Spec}(\mathbb{Z})} \mathbb{P}_{\mathbb{Z}}^n$$

Before we come to the proof of properness now, there is one last notion to present.

Definition 3.4. Let $x \in X$ be a point in a scheme (or more generally, a topological space). A point $x' \in X$ is said to *specialize* x , if it is contained in the closure $x' \in \overline{\{x\}}$.

The next lemma is directly from [Har77, p. II.4.5].

Lemma 3.5. *Let $f : X \rightarrow Y$ be a quasi-compact morphism. Then $f(X)$ is closed if and only if it is stable under specialization.*

Proof. The implication \Leftarrow is clear. It suffices to show that $f(X) \cap V \subseteq V$ is closed for all affine opens $V \subseteq Y$.

Note that the preimage $f^{-1}(V)$ is quasi-compact, hence has a finite cover of affine opens $U_i \subseteq X$. Now let $V_i = \overline{f(U_i)}$ be the closed subscheme of V with the canonical (reduced) scheme structure⁶. Since V is affine, also V_i is affine. Note that now it suffices to show that $f(U_i) \subseteq V_i$ is closed.

In other words, we have reduced the situation to the case that

$$f' = f|_{U_i} : U_i = \text{Spec}(A) \rightarrow V_i = \text{Spec}(B)$$

⁶As in the Lecture Notes, Section 5.6.

is a morphism between affine schemes with dense image. We want to show that $f'(U_i)$ is already V_i , i.e. $V_i \subseteq f(U_i)$.

Consider some $\mathfrak{p} \in V_i$. By Zorn's Lemma, there is a minimal prime ideal $\mathfrak{p}' \subseteq \mathfrak{p}$ in the ring B . Note that \mathfrak{p} is a specialization of \mathfrak{p}' . Hence, it suffices to show that $\mathfrak{p}' \in f'(U_i)$. Note that $B_{\mathfrak{p}'}$ must be a field, otherwise we could take a proper nonzero prime ideal of $B_{\mathfrak{p}'}$ and its preimage under $B \rightarrow B_{\mathfrak{p}'}$ would be a smaller prime ideal in B .

Since $f' : \text{Spec}(A) \rightarrow \text{Spec}(B)$ has dense image, we find that $B \rightarrow A$ is injective. Consider A as a B -algebra. Let \mathfrak{q} be a prime ideal of $A \otimes_B B_{\mathfrak{p}'}$ (this is not the zero ring, as $B_{\mathfrak{p}'}$ is a flat B -module and so the inclusion $B \rightarrow B_{\mathfrak{p}'}$ induces an inclusion $B_{\mathfrak{p}'} \rightarrow A \otimes_B B_{\mathfrak{p}'}$).

Taking the preimage of \mathfrak{q} under the map $A \rightarrow A \otimes_B B_{\mathfrak{p}'}$ now gives a prime ideal $\mathfrak{q}' \leq A$. Since $\mathfrak{q} \cap B_{\mathfrak{p}'} = \{0\}$ (here we use that $B_{\mathfrak{p}'}$ is a field), find $\mathfrak{q}' \cap B = \mathfrak{p}'$, thus \mathfrak{q}' maps to \mathfrak{p}' under $\text{Spec}(A) \rightarrow \text{Spec}(B)$. This shows $\mathfrak{p}' \in f'(U_i)$ and the claim follows. \square

The next lemma is now the decisive statement that will allow us to show that $\mathbb{P}_R^n \rightarrow \text{Spec}(R)$ is closed. It is also the place where things get somewhat ugly, and we require a good deal of commutative algebra to prove it.

Lemma 3.6. *Let $\mathfrak{p} \in \text{Proj}(R[x_0, \dots, x_n])$ and let $\mathfrak{q} \leq R$ be a prime ideal such that $\mathfrak{p} \cap R \subseteq \mathfrak{q}$. Then there some i such that no αx_i^m is in $\mathfrak{b} := \mathfrak{p} + \mathfrak{q}R[x_0, \dots, x_n]$, for any $\alpha \in R \setminus \mathfrak{b}$ and any $m \in \mathbb{N}$.*

Proof. Assume for a contradiction that there is $m \in \mathbb{N}$ such that $\alpha_i x_i^m \in \mathfrak{b}$ for all i and some $\alpha_i \in \mathfrak{b} \setminus R$. Since $\mathfrak{b} \cap R = \mathfrak{q}$ is prime, have that $\alpha := \prod_i \alpha_i \notin \mathfrak{b}$ and further $\alpha^n \notin \mathfrak{b}$ for all $n \in \mathbb{N}$. Furthermore, we obviously have $\alpha x_i^m \in \mathfrak{b}$ for all i .

Consider now the vector $(w_i)_{i < N}$ containing all monomials of degree $(n+1)m$. By assumption, all $\alpha w_i \in \mathfrak{b}$. Since \mathfrak{p} is homogeneous, observe that by definition of \mathfrak{b} , there are $r_{ij} \in \mathfrak{q}$ such that

$$\alpha w_i - \sum_{j < N} r_{ij} w_j \in \mathfrak{p}$$

Working modulo \mathfrak{p} , we see that $Aw = \alpha w$ where $A \in (\mathfrak{b}/\mathfrak{p})^{N \times N}$ is a matrix with coefficients in $\mathfrak{b}/\mathfrak{p}$.

Now observe that no power of α is in $\mathfrak{b}/\mathfrak{p}$ (as mentioned before). Hence there exists a prime ideal⁸ in R/\mathfrak{p} containing $\mathfrak{b}/\mathfrak{p}$ and not containing α . Localizing at that prime ideal gives a local ring S with maximal ideal \mathfrak{l} . Now we continue in S , replacing w and A/α by their images under $R \rightarrow S$. So $w \in S^N$ and $A/\alpha \in \mathfrak{l}^{N \times N}$. Note that we still have $(A/\alpha)w = w$.

wlog S is Noetherian, otherwise continue with the ring

$$\tilde{S} := (\mathbb{Z}/\text{char}(S)\mathbb{Z})[A/\alpha, x]$$

⁷Since a monomial of degree $(n+1)m$ in $n+1$ variables is divisible by x_i^m for at least one i , by the pigeonhole principle.

⁸By the usual argument, i.e. take a preimage of a prime ideal under the map $R \rightarrow R/\mathfrak{p} \rightarrow (R/\mathfrak{p})_\alpha$.

generated by the coefficients of A/α and w (this is Noetherian, as it is a quotient of a polynomial ring in finitely many variables).

Now equip S with the \mathfrak{l} -adic topology. Note that S is Noetherian and local, thus the Krull intersection theorem [Cla15, p. 8.41] shows that the \mathfrak{l} -adic topology is Hausdorff and we find

$$w = \lim_{i \rightarrow \infty} w = \lim_{i \rightarrow \infty} \frac{A^i}{\alpha^i} w = \left(\lim_{i \rightarrow \infty} \frac{A^i}{\alpha^i} \right) w = 0w = 0$$

since $(A/\alpha)^i$ has coefficients in \mathfrak{l}^i , thus converges to 0 as $i \rightarrow \infty$.

Thus $w \equiv 0 \pmod{\mathfrak{p}}$ and so $x_i^N \equiv 0 \pmod{\mathfrak{p}}$, i.e. $x_i^N \in \mathfrak{p}$ for all i . However, since \mathfrak{p} is prime, this implies $R[x_0, \dots, x_n]_+ = \langle x_0, \dots, x_n \rangle \subseteq \mathfrak{p}$, contradicting the assumption. \square

As we will see in the next proof, this lemma shows that if $\mathbb{P}_R^n \rightarrow \text{Spec}(R)$ maps a point \mathfrak{p} to a point \mathfrak{q} , then it also maps a specialization of \mathfrak{p} to any specialization of \mathfrak{q} . From this, we can derive the next proposition.

Proposition 3.7. *The morphism $\mathbb{P}_R^n \rightarrow \text{Spec}(R)$ is closed.*

Proof. Denote $\mathbb{P}_R^n \rightarrow \text{Spec}(R)$ by ϕ . Consider a closed set $V_+(\mathfrak{a}) := \mathbb{P}_R^n \setminus D_+(\mathfrak{a})$ given by a homogeneous ideal $\mathfrak{a} \leq R[x_0, \dots, x_n]$. By Lemma 3.5, it suffices to show that $\phi(V_+(\mathfrak{a}))$ is closed under specialization (note that $\mathbb{P}_R^n \rightarrow \text{Spec}(R)$ is quasi-compact, e.g. by Proposition 2.8).

Consider $\mathfrak{q} \in \phi(V_+(\mathfrak{a})) \subseteq \text{Spec}(R)$ and a prime ideal \mathfrak{q}' that specializes \mathfrak{q} , i.e. $\mathfrak{q}' \supseteq \mathfrak{q}$. Then there is a $\mathfrak{p} \in V_+(\mathfrak{a})$ with $\mathfrak{p} \cap R = \mathfrak{q}$, in particular $\mathfrak{a} \subseteq \mathfrak{p}$. We want to show that $\mathfrak{q}' \in \phi(V_+(\mathfrak{a}))$.

Note that by Lemma 3.6, there is i such that the multiplicative set

$$T := \{\alpha x_i^m \mid \alpha \in R \setminus \mathfrak{q}', m \in \mathbb{N}\}$$

has empty intersection with the ideal $\mathfrak{b} := \mathfrak{p} + \mathfrak{q}'R[x_0, \dots, x_n]$.

Hence, the ring $T^{-1}(R[x_0, \dots, x_n]/\mathfrak{b})$ is nonzero, thus has a prime ideal. Taking its preimage under

$$R[x_0, \dots, x_n] \rightarrow R[x_0, \dots, x_n]/\mathfrak{b} \rightarrow T^{-1}(R[x_0, \dots, x_n]/\mathfrak{b})$$

yields a prime ideal \mathfrak{p}' such that $x_i \notin \mathfrak{p}'$ and $\mathfrak{b} \subseteq \mathfrak{p}'$. Clearly have that $\mathfrak{q}' \subseteq \mathfrak{p}'$ and since $\mathfrak{p}' \cap T = \emptyset$, find that $\mathfrak{p}' \cap R = \mathfrak{q}'$. By Lemma 1.6, assume wlog that \mathfrak{p}' is homogeneous. Now have a homogeneous prime ideal \mathfrak{p}' with $\mathfrak{a} \subseteq \mathfrak{p} \subseteq \mathfrak{p}'$, i.e. $\mathfrak{p}' \in V_+(\mathfrak{a})$ and $\phi(\mathfrak{p}') = \mathfrak{p}' \cap R = \mathfrak{q}'$. Thus $\mathfrak{q} \in \phi(V_+(\mathfrak{a}))$ and the claim follows. \square

I must say, I find this proof and also the more geometric proof later (Proposition 4.2) extremely fascinating. In particular, I like how generic points are quite important for the proof. It also reminds me of the only classical proof of an equivalent statement (projections from projective space are closed) I have ever seen. The idea was - more or less - to consider points $y \in \text{im}(f) \subseteq \mathbb{P}_k^n$ with preimages $x \in X \subseteq \mathbb{P}_k^m$ and deduce (using Hilbert's Nullstellensatz) that there is some “generic preimage” $\tilde{x} \in \mathbb{P}_K^m$ in projective space over the algebraic closure $K = \overline{k(Y)}$ of the “generic point” $\tilde{y} = [y_0 : \dots : y_n] \in \mathbb{P}_K^n$.

A “partial evaluation homomorphism” (i.e. not defined on the whole domain) $K \dashrightarrow k$ can then be used to “evaluate” the “generic preimage point” on each image point. The core of that proof is exactly constructing this “partial evaluation homomorphism”, which corresponds exactly to Lemma 3.6.

But now enough of talking, here is the main corollary, which is also the main result of the miniproject.

Corollary 3.8. *The morphism $\mathbb{P}_R^n \rightarrow \operatorname{Spec}(R)$ is universally closed.*

Proof. Use Lemma 3.1, so consider an affine base change $f_{\operatorname{Spec}(S)} : \mathbb{P}_R^n \times_{\operatorname{Spec}(R)} \operatorname{Spec}(S) \rightarrow \operatorname{Spec}(S)$. By Lemma 3.3, have that $\mathbb{P}_R^n \times_{\operatorname{Spec}(R)} \operatorname{Spec}(S) \cong \mathbb{P}_S^n$ as schemes over S , hence $f_{\operatorname{Spec}(S)}$ is isomorphic to $\mathbb{P}_S^n \rightarrow \operatorname{Spec}(S)$. This morphism is closed by Proposition 3.7 and the claim follows. \square

Corollary 3.9. *Projective space \mathbb{P}_R^n over $\operatorname{Spec}(R)$ is proper.*

Corollary 3.10. *Let k be an algebraically closed field. Then projective space \mathbb{P}_k^n over $\operatorname{Spec}(k)$ is a complete variety.*

4 Valutive criterion of properness

Instead of using some magical ad-hoc argument as before, there is also the following nice characterization of the notion of properness. We will omit the proof here, but present the statement as it can give more geometric intuition on properness and why \mathbb{P}_R^n is proper.

Proposition 4.1. *Let X be Noetherian and $f : X \rightarrow Y$ a morphism of finite type. The following are equivalent*

- *f is proper*
- *For every valuation ring R with field of fractions $K = \operatorname{Frac}(R)$ and all morphisms $\operatorname{Spec}(R) \rightarrow Y$, $\operatorname{Spec}(K) \rightarrow X$ that make the diagram*

$$\begin{array}{ccc} \operatorname{Spec}(K) & \longrightarrow & X \\ \downarrow & & \downarrow f \\ \operatorname{Spec}(R) & \longrightarrow & Y \end{array}$$

commute, there exists a unique compatible morphism $\operatorname{Spec}(R) \rightarrow X$.

Proof. Omitted, see e.g. [Har77, p. II.4.7] or [Stacks, Tag 0BX5]. \square

Proposition 4.2. *The morphism $\mathbb{P}_R^n \rightarrow \operatorname{Spec}(R)$ is proper.*

Alternative Proof. Since properness is preserved under base change, by Lemma 3.3 it suffices to show the statement for $\mathbb{P}_{\mathbb{Z}}^n \rightarrow \operatorname{Spec}(\mathbb{Z})$.

Apply Proposition 4.1. Let R be a valuation ring, $K = \operatorname{Frac}(R)$ and assume we have morphisms $\operatorname{Spec}(R) \rightarrow Y$, $\operatorname{Spec}(K) \rightarrow X$ such that the diagram

$$\begin{array}{ccc}
\mathrm{Spec}(K) & \longrightarrow & X \\
\downarrow & & \downarrow f \\
\mathrm{Spec}(R) & \longrightarrow & Y
\end{array}$$

commutes. Note that $\mathrm{Spec}(K) = \{\langle 0 \rangle\}$, so let $\xi \in X$ be the image of $\langle 0 \rangle$ under $\mathrm{Spec}(K) \rightarrow X$. Since $\langle x_0, \dots, x_n \rangle \not\subseteq \xi$, there is $x_i \notin \xi$. Now let

$$f_j := \begin{cases} x_j & \text{if } x_j \notin \xi_1 \\ x_j - x_i & \text{if } x_j \in \xi_1 \end{cases}$$

Thus all f_j are homogeneous of degree 1 with $\langle f_j \mid j \rangle = \langle x_0, \dots, x_n \rangle$. It follows that $X = \bigcup_j D_+(f_j)$ is a cover by affine opens such that $\xi \in \bigcap_j D_+(f_j)$. Now possibly apply a linear automorphism $f_j \rightarrow x_j$, so have wlog $f_j = x_j$. In particular, find $x_j \in \mathcal{O}_{X, \xi_1}^*$.

The morphism $\mathrm{Spec}(K) \rightarrow X$ now gives an inclusion $k(\xi) \subseteq K$. Since $x_j \in \mathcal{O}_{X, \xi}^*$, observe that $g_{ij} := x_i/x_j \in K$ is well-defined and nonzero with $g_{ij}g_{jk} = g_{ik}$.

As R is a valuation ring, we find k such that g_{k0} is the smallest element (w.r.t. divisibility by R) among g_{00}, \dots, g_{n0} . So we see that $g_{jk} = g_{j0}/g_{k0} \in R$ for all i . In particular, we find a ring homomorphism

$$\mathbb{Z} \left[\frac{x_0}{x_k}, \dots, \frac{x_n}{x_k} \right] \rightarrow R, \quad \frac{x_j}{x_k} \mapsto g_{jk}$$

that is compatible with the field inclusion $k(\xi) \subseteq K$.

The induced morphism

$$\mathrm{Spec}(R) \rightarrow \mathrm{Spec}(\mathbb{Z} \left[\frac{x_0}{x_k}, \dots, \frac{x_n}{x_k} \right]) = D_+(x_k) \subseteq X$$

is now a compatible morphism $\mathrm{Spec}(R) \rightarrow X$.

It is not hard to show that the morphism is unique⁹, and the claim follows. \square

Note that in some way, this is the same proof as before. The core idea - namely the choice of the smallest element g_{k0} (w.r.t. divisibility by R) - more or less achieves the same effect as the more complicated ideal argument from Lemma 3.6.

Conclusion

In this work, we have seen how to construct the scheme $\mathrm{Proj}(S)$ given a graded ring S . Furthermore, we have peeked into its properties, and used it to prove an important statement about projective space. Additionally, we have tried to explain a little bit what

⁹In fact, the statement that there is at most one such morphism is equivalent to $\mathbb{P}_R^n \rightarrow \mathrm{Spec}(R)$ being separated (by [Stacks, Tag 01L0]), so follows from Proposition 2.2.

is going on in the proof, and compared two different versions of proof. The first proof is my own work¹⁰, while the second proof is the standard proof found in many textbooks.

If one continues that line of thought, the next step would probably be to study *projective morphisms*, i.e. morphisms that factor through projective space via a closed immersion, and show that they are always proper. After that, it seems like an interesting idea to examine the phenomenon of properness closer. For example [Har77] mentioned that not all proper morphisms are projective, so it might be instructive to find examples for that and study in which other situations one gets a projective morphism.

Finally, another line of continuing the work would be to study the cohomology of $\mathrm{Proj}(S)$, and how it relates to the ring S . From the lecture, we already know that projective space $\mathbb{P}_{\mathbb{Z}}^n$ has a first Čech-cohomology group isomorphic to \mathbb{Z} . Starting from that, it would be interesting to see what the cohomology group of $\mathrm{Proj}(S)$ for other graded rings S is. A natural first step would be to consider $S = R[x_0, \dots, x_n]/\mathfrak{a}$ for a homogeneous ideal \mathfrak{a} , i.e. study the cohomology of closed subschemes of \mathbb{P}_R^n . This can already become quite complicated, as for example the case of Elliptic Curves shows. In the end, it will be interesting if the representation of a scheme as $\mathrm{Proj}(S)$ gives us better access to computing cohomology as the standard way to cover it by affine opens.
